ABSTRACT

Background: Aims: Future prediction of Chronic Kidney Disease (CKD) patients in rural India based on 2 year observation study of patients attending nephrology department in National Institute of Medical Sciences, Shobha Nagar, Jaipur, Rajasthan, India. Methods: This is a 2-year retrospective survey conducted at NIMS Medical College and Hospital- a tertiary hospital in rural area close to Jaipur. All End Stage Renal Disease (ESRD) patients attending nephrology department for dialysis were studied to know the pattern of CKD-ESRD in rural India. Result: A total of 100 CKD-ESRD patients attended to dialysis unit of nephrology department between Jan 2014-Jan 2016, out of which 32 died (P=0.0026; highly significant), 10 changed the dialysis centre, 7 underwent successful Renal transplantation, 8 were on continuous ambulatory peritoneal dialysis (CAPD) and remaining 43 were on regular maintenance hemodialysis. Conclusion: Increased mortality in CKD-ESRD patients is due to poor compliance related to financial limitations.

Keywords: Chronic Kidney Disease, End Stage Renal Disease, continuous ambulatory peritoneal dialysis, renal replacement therapy, renal transplantation.

INTRODUCTION

Chronic Renal Failure is generally considered as the disease of old age, especially in patients with long standing diabetes mellitus and hypertension,[5] whereas in children and young adults it is due to Glomerulonephritis, interstitial nephritis, obstructive uropathy.[2] Complications like uremic pericarditis, cardiac tamponade, seizures, intracranial bleeding are considered as a dangerous in a patients with chronic renal failure.[1]

Numbers of prevalent CKD patients will continue to rise, reflecting the growing elderly population and increasing numbers of patients with diabetes and hypertension. This rise is a problem of concern in a developing country like India whose health care and public sector economy is limited.[9] The epidemiology of CKD in India is very different from the West. Patients are roughly two decades younger, and a substantial proportion present with small kidneys, so the etiology of CKD is unclear.4 In addition to that, there is substantial rise in CKD cases from rural areas thus narrowing the gap between urban and rural area prevalence of CKD.[10,11] As numbers of CKD patients in rural areas increase, primary care practitioners will be confronted with management of the complex medical problems unique to patients with chronic renal impairment due to unavailability of super speciality services and infrastructure at ground level. The nephrologist rarely manages the medical needs of CKD patients in rural areas.

CKD is defined as the presence of kidney damage, manifested by abnormal albumin excretion or decreased kidney function, quantified by measured or estimated glomerular filtration rate (GFR), that persists for more than three months.[3] Practical approach in the office is to estimate GFR (estimated GFR or eGFR) from the serum creatinine concentration, using Cockcroft-Gault method. Estimated GFR <15ml/min/1.73m² is considered as ESRD which needs renal replacement therapy for survival which may be either continuous ambulatory peritoneal dialysis (CAPD) or maintenance hemodialysis (MHD) or Renal Transplantation (RT). Chronic Renal Failure is a disease which needs proper understanding by the family members. Illiteracy, poor follow-up, non-compliance to dialysis, denial of transplantation are common annoy in rural areas thus leading to increased morbidity and mortality.[5]
MATERIALS AND METHODS

This is a 2 year retrospective survey conducted at NIMS Medical College and Hospital- a tertiary hospital in rural area which is close to Jaipur. All End Stage Renal disease (ESRD) patients attending nephrology department were studied. A total of 100 CKD-ESRD patients attended to nephrology department between January 2014-January 2016, the youngest being 10 year old and the oldest being 75 year old. Investigations like complete hemogram, blood urea, serum creatinine, serum electrolytes, serum calcium, serum phosphorus, parathyroid hormone levels and abdominal sonogram for kidney size/echotexture were done in this study. Staging of CKD is done through Cockcroft-Gault method.

RESULTS

In our study of 100 patients, 61(61%) were males and 39(39%) were females. The mean ± SD age of all participants was 42.5601 ± 14.97298 years (range 10–75 years). Etiology of 100 CKD patients in our region is given in [Table 1], with diabetes being most common (40%).

Out of these 100 patients, 32 died, 10 changed the dialysis centre, 7 underwent successful renal transplantation, 8 were on continuous ambulatory peritoneal dialysis (CAPD) and remaining 43 were on regular maintenance hemodialysis- three sessions per week, each session lasting for 4-6 hours. (P<0.0001; very highly significant).

Figure 1:
DISCUSSION

National Health and Nutrition Examination Survey (NHANES) data showed that over the last decade (from 1994 to 2004) prevalence of CKD increased from 14.5 % to 16.8% (15% rise). Stage wise prevalence is stage 1- 5.7%, stage 2- 5.4%, stage 3- 5.4%, stage 4/- 0.4%. [7] Mani, working in Chennai, South India, estimated a prevalence of chronic renal failure of 0.16 per cent in the community in 2003; applying the Modification in Diet in Renal Disease (MDRD) equation for GFR estimation in 2005, 0.86 per cent were found to have a GFR <80ml/min/1.73m2.[8]

In our study of 100 patients, 61% were males and 39% were females. This prevalence almost matches with previous studies by singh et al (55.1% males and 44.9% females).[9] The mean ± SD age of all participants was 42.5601± 14.97298 years. This is in line with singh et al (45.22 ± 15.2 years) and anupama et al (39.88 ± 15.87 years).[10,11] Diabetic nephropathy (40%) is the most common etiology in our patients which is also the most common cause of CKD all over the world and India.[14] The second most common cause is idiopathic/not otherwise specified/unknown (17%), this could probably be due to relying on non-evidence based medicine, indigenous drug abuse whose usage is more rural areas. This is well supported by Almaguer M et al who did his work on unknown cause of CKD in rural areas of Andhra Pradesh state in India.[15]

In our study, among 32 patients died, 8 patients (25%) were those who stopped access to dialysis facility completely and 16 (50%) were those who use to undergo haphazard dialysis (less than two sessions per week, under dialysed-presenting with fluid overload, acidosis etc.) due to poverty, influence of quacks, relying on non-evidence based medicine (homeopathy, ayurvedic, herbal-Image-1). So, 75% of deaths in rural areas were related to illiteracy, lack of awareness, affordability. These reasons were highlighted previously by Mani M K in 199212 and Sharma et al in 2000.[13] The only way of prolonging life in Stage 5- ESRD is renal replacement therapy. But the monthly cost of hemodialysis/peritoneal dialysis is around 20,000 INR(Indian National Rupee). Renal transplantation costs around 1-2 lakhs in government facility and 5-8 lakhs in a private facility, besides this cost of immunosuppression is around 10,000 INR/month. An average Indian, even an upper middle class can’t afford this. The worst part is there is maldistribution of these facilities with most of the facilities/nephrology consultation exists in bigger cities. Thus CKD-ESRD had become sorrow for rural population in India. Generally in India, CAPD is advised in old age (>60-65yrs).[16] People living in remote areas limited to primary health centre services who can’t attend to dialysis centers regularly. Hemodialysis(HD) is mode of renal replacement in majority of patients. Renal transplantation which is the best renal replacement is still limited in only major cities. However with increasing awareness, the direction of CKD in rural India is holding promise but still needs lot of improvement.

CONCLUSION

75% of CKD-ESRD deaths in rural areas were due to poor compliance of renal replacement therapy because of financial limitations, illiteracy, false counselling by quacks. Among these the most common cause of death is pulmonary edema(43.75%) which was seen in patients who wished to continue medical management instead of hemodialysis. Patients on proper renal replacement therapy showed good quality of life during their illness, however best among them were patients who underwent renal transplant. Hence, failing to take proper treatment in proper time increases mortality in CKD patients.

Limitations

Chronic illness like CKD should involve large number of patients and prolong follow up right from the beginning of CRF till death of patients to extract proper information which is lagging in our study.
